㉙ Dental pinning device.

㉚ The device has an elongated shank with a formation at one end for engagement with a latching-type hand-piece. At the other end the shank, which is of synthetic resin material, has a shearing neck 18 and is moulded around a metal shaft 20 to form a coating 21. The shaft 20 is integral with the threaded pin 19 which is screwed into the tooth.

The coating 21 conceals the metal pin, thus improving the appearance of the restoration. It also by engagement with the tooth limits the insertion of the pin and provides the resistance against which the neck 18 is sheared.

Fig.2

DENTAL PINNING DEVICE

The present invention relates to dental pinning devices which are used to insert pins into the structure of a broken or worn down tooth to receive a restoration or superstructure. The invention is particularly concerned with self-threading pins which are screwed  
5 into a pre-drilled hole in the tooth.

Various pinning devices have been described and are in use for insertion of a self-threading pin to act as an anchor for a restoration. In particular U.K. Patent Specification No. 1,482,681 describes a pinning device which comprises a shank of which one end  
10 is provided with a flat and a part-annular groove for engagement in conventional manner with a latching-type dental handpiece. The pin is formed integrally with the metal shank and is connected to the other end of the shank by a narrow neck. When the pin is screwed into the tooth and bottoms in the pre-drilled hole, continued rotation of  
15 the shank causes shearing of the neck and leaves the pin projecting from the tooth. This is thus a self-shearing pin. An improved form of integral pinning device which enables the pin to align itself in the pre-drilled hole is described in my U.K. Patent Specification No. 1,597,483.

20 There is also available on the market the Whaledent "Linkpin" dental pinning device in which the shank is moulded from a synthetic resin material and has at one end the flat and part-annular groove for latching into a hand-piece. The threaded pin is part of a metal portion which includes the shearing neck and has a spigot which is  
25 fitted into a bore in the end of the shank.

In this case, as in all the other known devices, when the threaded pin has been screwed into the tooth and has sheared off from the shank at the neck there is left projecting from the tooth a metal anchorage member which forms the foundation for the restoration.  
30 Whatever materials are used this frequently means that the anchorage member is visible through the restoration.

In accordance with the present invention there is provided a dental pinning device comprising a shank having at one end a formation for engagement with a latching-type dental handpiece and carrying at the other end, by way of a shearing neck, a threaded pin for screwing  
5 into a tooth, wherein the threaded pin is part of a metal end-piece which also includes an integral shaft of smaller diameter projecting from the pin and the shank and shearing neck are formed as a body of synthetic resin material and are attached to the end piece by moulding of the synthetic resin material around the shaft.

10 The shaft, with its coating of synthetic resin material, remains attached to the threaded pin when the neck shears and forms an anchor section projecting from the tooth, the threaded pin being buried within the tooth. Thus no metal parts are exposed and the coating can be of an optically dense material of suitable colour to  
15 completely conceal the presence of the metal pin and shaft. The quantity of metal required is so small that it is possible to use gold or other precious metal without excessive cost.

The presence of the coating may also be used to control the shearing action since engagement of the end of the coating with the  
20 surface of the tooth will increase the torque acting and produce shearing of the pin, thus replacing the usual engagement of the pin with the bottom of the hole and preventing over-insertion of the pin. This assumes, as will normally be the case, that the coating has an outside diameter greater than that of the thread of the pin.

25 To ensure a good bond between the metal end-piece and the synthetic resin material, the shaft can be knurled or pitted and may be of non-cylindrical shape. The end-piece can be mounted in a mould and the synthetic resin material cast around the shaft while the body is being formed. In the preferred method of manufacture a plurality  
30 of pinning devices are formed simultaneously in a single mould in which the shanks extend laterally from two supporting branches which extend in alignment with each other from opposite sides of a central stem. The branches can be removed from the stem and supplied to the dentist who then separates a pinning device from one of the branches  
35 whenever he requires one.

The invention will now be described in more detail with the aid of an example illustrated in the accompanying drawings, in which

Fig.1 is a view of an injection moulding comprising a multiplicity of pinning devices in accordance with the invention, and

5 Fig. 2 is a detail, partially in section, of the end of a single pinning device which carries the threaded pin.

The moulding shown in Fig. 1 comprises a stem 10 with two opposite branches 11 and 12 aligned with one another. Each of the branches 11 and 12 has ten pinning devices 13 projecting laterally  
10 from one side of the branch. Each pinning device 13 is complete with a metal end-piece 14 which is incorporated into the moulding as will be described in more detail below. The branches 11 and 12 and the stem 10 have bosses 15 which serve for ejection of the moulding from the mould. The branches 11 and 12 can be broken from the stem 10 at  
15 the junctions 16 and 17, respectively.

Each of the pinning devices 13 has a tapering shank composed of synthetic resin material. Reference may be made to U.K. Patent Specification No. 1,597,483 for details of the shape of the shank, including the flat and part-annular groove for attachment to a dental  
20 hand-piece. The present shank differs only in the material of which it is made. At the other end of the shank is a narrow neck 18, shown in Fig.2, which is also composed of synthetic resin material and forms the shear point for the pinning device.

As seen in Fig.2, the end-piece 14 consists of a threaded pin  
25 19 and an integral shaft 20 of smaller diameter. Before the end-piece 14 is placed in the mould, the surface of the shaft 20 is pitted to enable the synthetic resin to key onto it. During the moulding operation in which the shank and neck are formed there is also formed a coating or sleeve 21 over the shaft 20 which secures the end piece  
30 14 to the shaft. The coating or sleeve 21 may be of slightly larger diameter than the threads of the pin 19. Thus the screwing of the pin 19 into a pre-drilled hole in the tooth is terminated by abutment of the sleeve 21 against the tooth followed by shearing of the neck 18 due to the increased torque. The anchor section left projecting

from the tooth is thus entirely covered by the synthetic resin material which may be chosen to conceal the metallic end piece while providing a good bond with the restoration. For the latter purpose it is evident that various different shapes may be used.

CLAIMS:

1. A dental pinning device comprising a shank having at one end a formation for engagement with a latching-type dental hand-piece and carrying at the other end, by way of a shearing neck, a threaded pin for screwing into a tooth, wherein the threaded  
5 pin is part of a metal end-piece which also includes an integral shaft of smaller diameter projecting from the pin and the shank and shearing neck are formed as a body of synthetic resin material and are attached to the end piece by moulding of the synthetic resin material around the shaft.
- 10 2. A device as claimed in claim 1 in which the synthetic resin material moulded around the shaft has an outside diameter greater than that of the thread of the pin.
3. A device as claimed in claim 1 in which the shaft has a roughened surface to key the synthetic resin material to the shaft.
- 15 4. A device as claimed in claim 1 in which the shank is of non-cylindrical shape.
